AAV-mediated gene therapy for haemophilia A (HA)

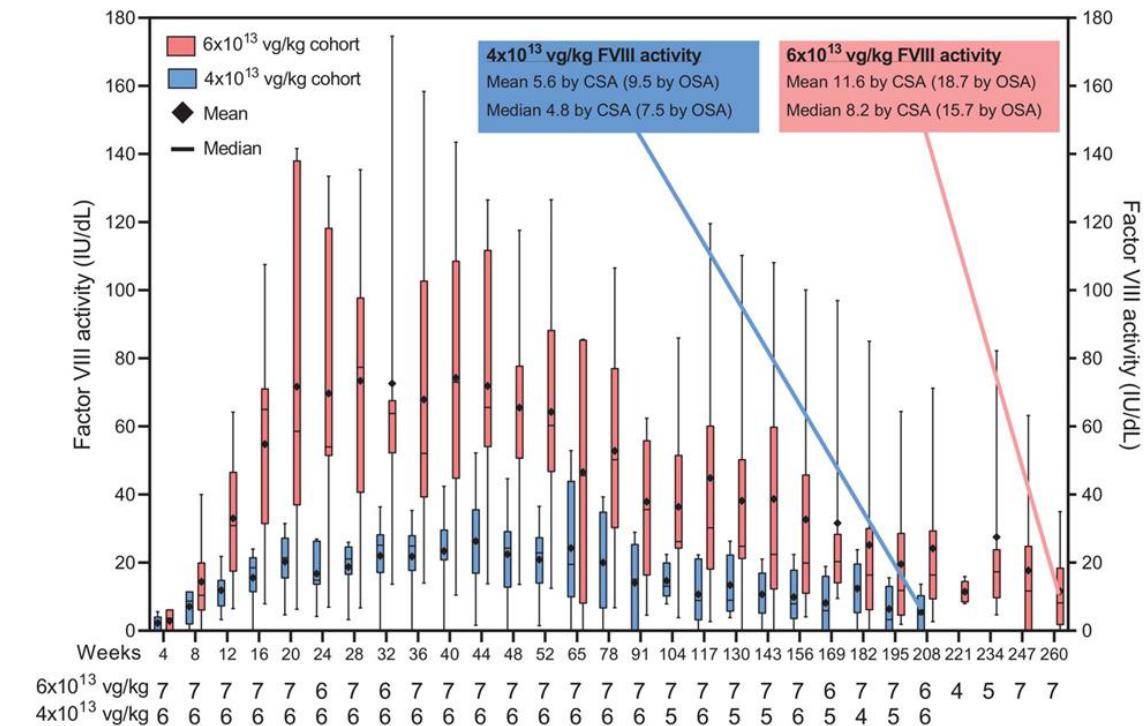

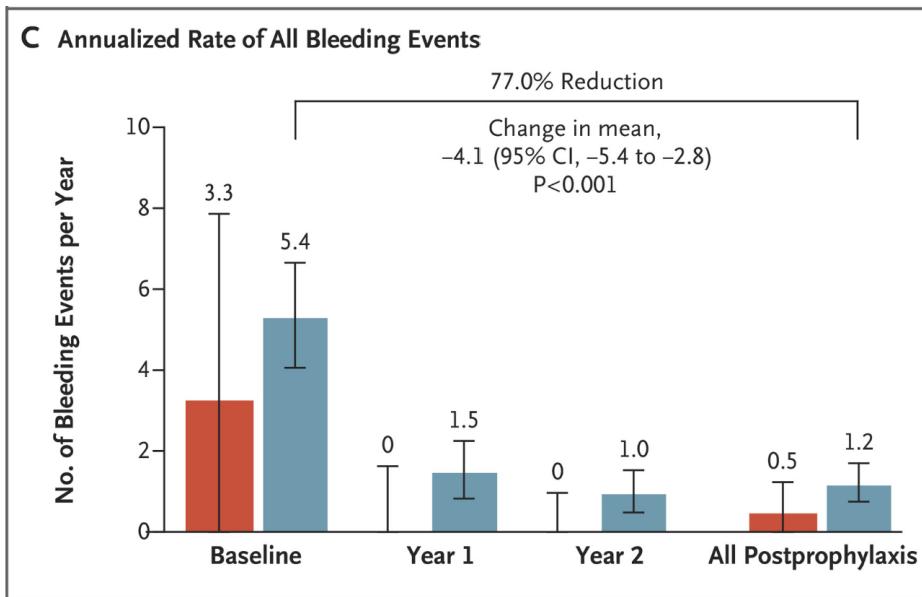

Haemophilia A (HA) is a congenital bleeding disorder caused by a **defect in coagulation FVIII** and affecting 1/5000 male birth

- Current **AAV-mediated gene therapy** enables expression of **transgenic FVIII**
- **First gene therapy** product EMA/FDA approved with valoctocogene roxaparvovec

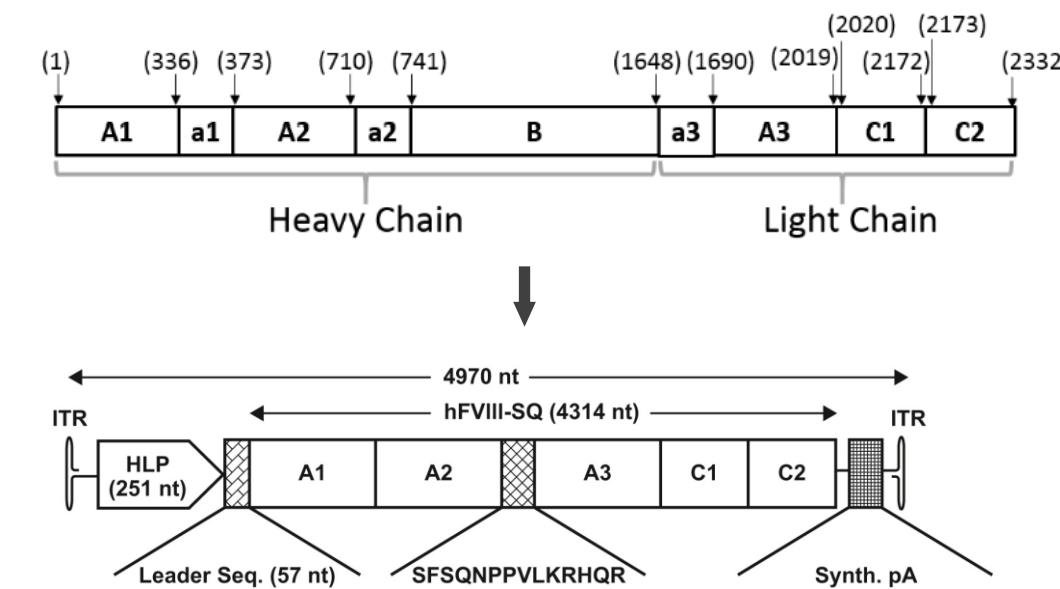

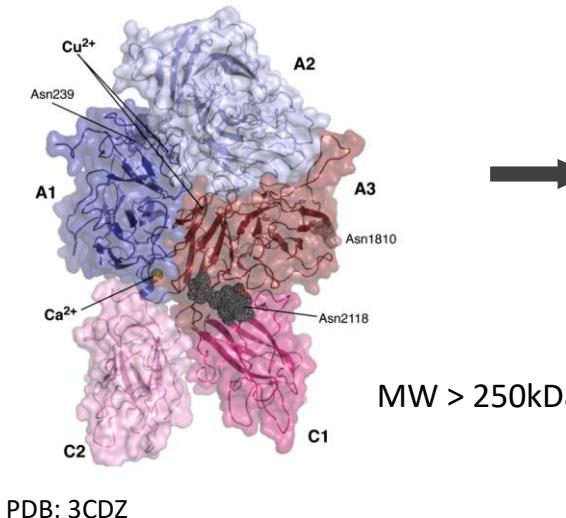

AAV-mediated gene therapy for haemophilia A (HA)

- valoctocogene roxaparvovec demonstrated clinical efficacy with significantly reduced bleeding rate in treated patients (Genr8-3)
- Progressive loss of transgenic expression overtime

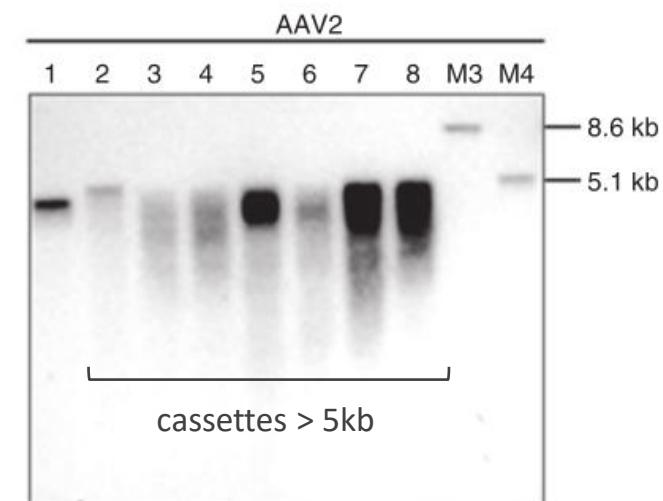

AAV-mediated gene therapy for haemophilia A (HA)

FVIII coding sequence **exceed the capacity** of transgene compatible with AAV capsid packaging capacity

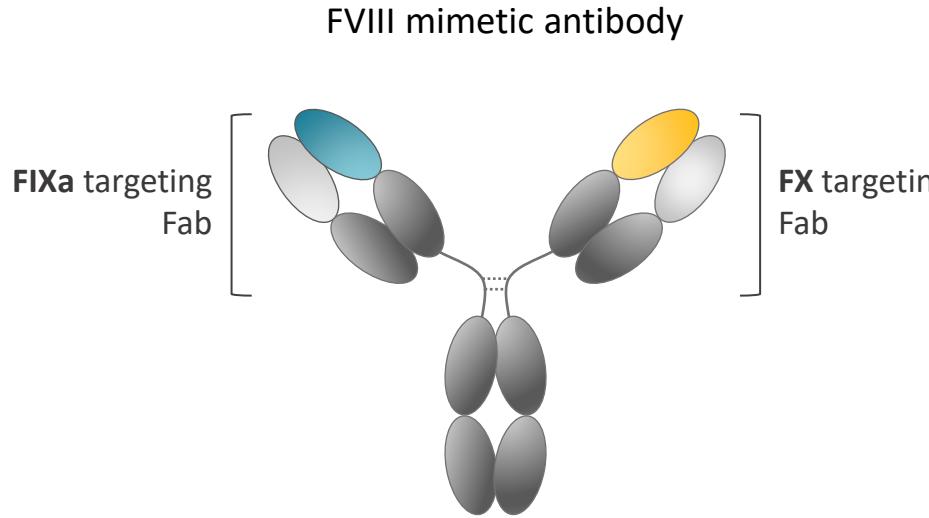

Coding seq. ~ 7kb

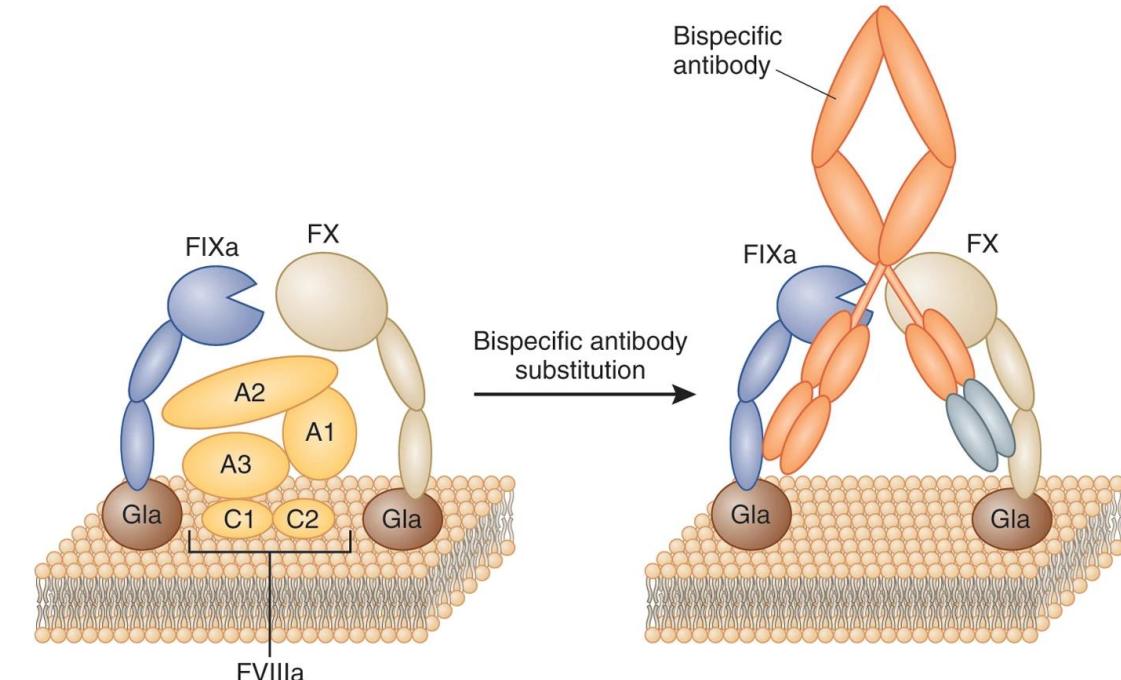

- ⇒ Requires the use of **oversized expression cassettes** above the packaging limit of AAV capsids
- ⇒ **Minimal space for regulatory elements**

Alternative gene therapy approach for HA

- Pioneered with the development of emicizumab
- Bypass FVIII deficiency to restore the coagulation cascade
- Efficient in Haemophilia A patient with and without FVIII neutralizing inhibitors

Alternative gene therapy approach for HA

- Pioneered with the development of emicizumab
- Bypass FVIII deficiency to restore the coagulation cascade
- Efficient in Haemophilia A patient with and without FVIII neutralizing inhibitors

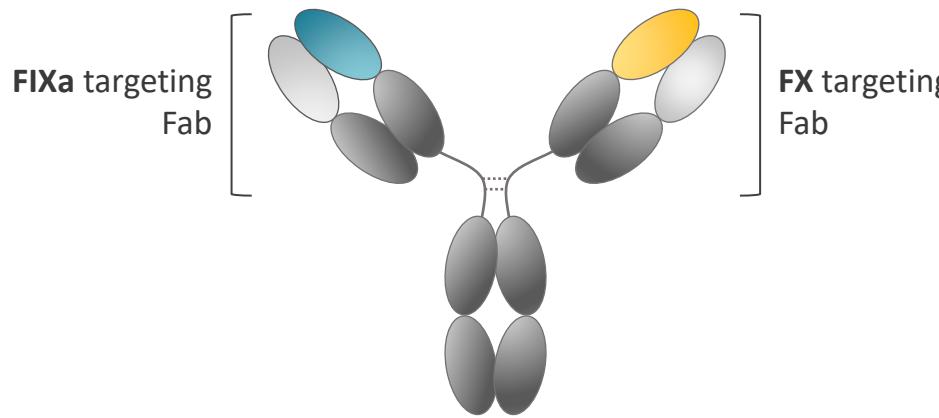

⇒ Strong potential of antibody engineering

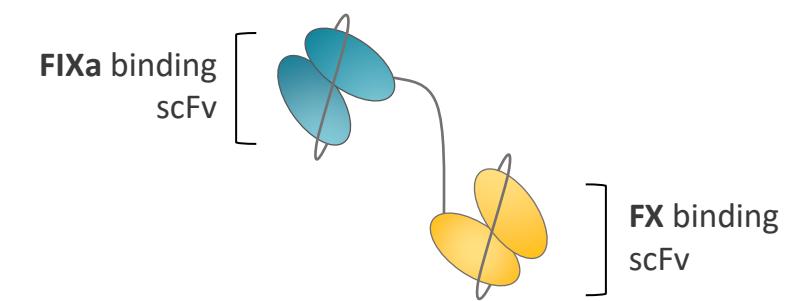

⇒ Can we combine the therapeutic potential of FVIII mimetic antibodies with AAV-mediated gene therapy ?

Bi8 – A single chain FVIII mimetic antibody

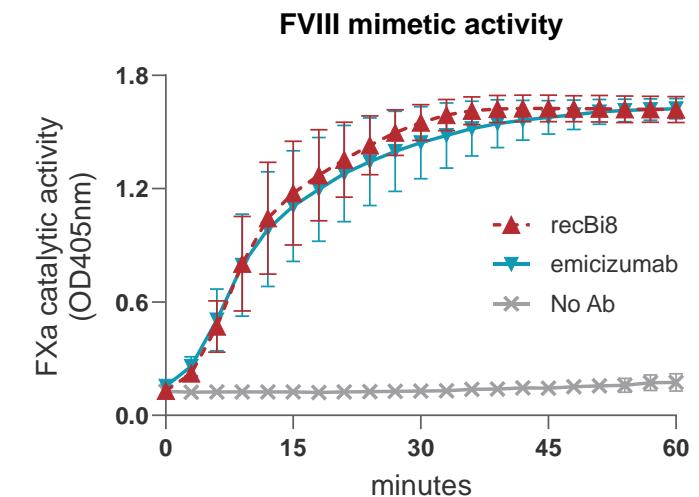

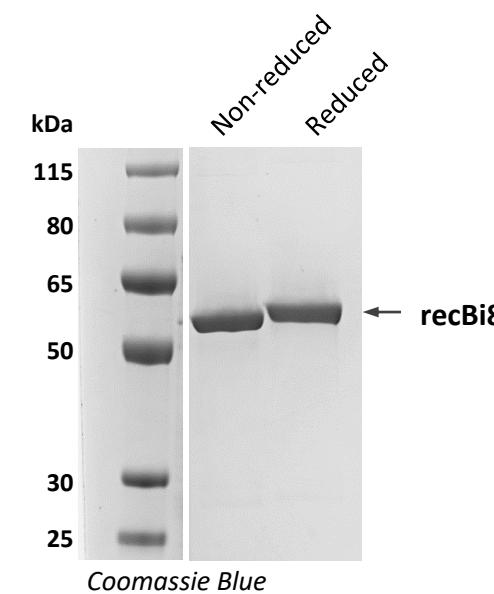

“Full-sized” FVIII mimetic antibody

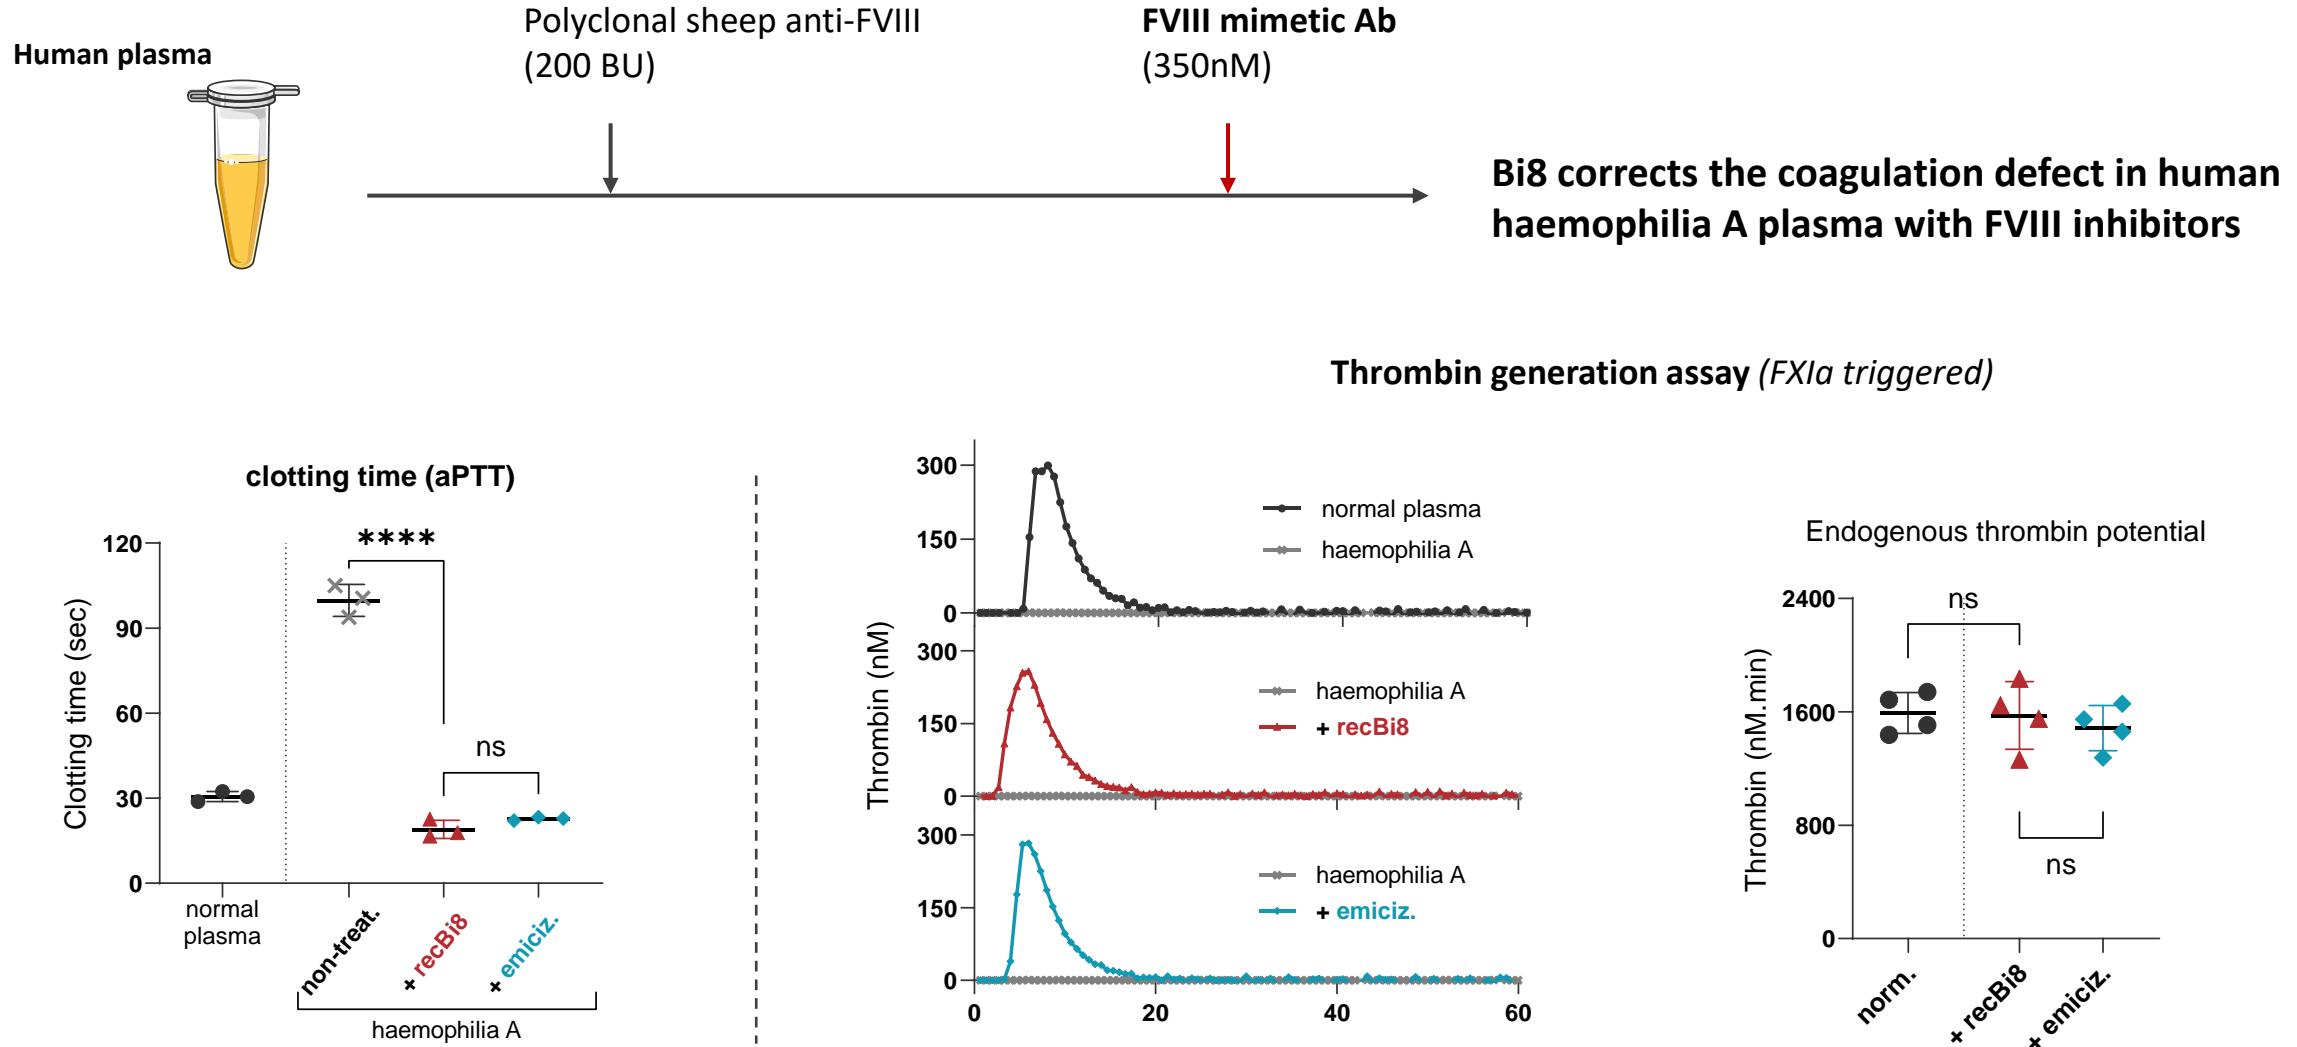

Bi8 – single chain FVIII mimetic antibody

- Single chain FVIII mimetic antibody
- Discrete band at 54.5 kDa when produced in Expi293 mammalian cells
- Shows efficient FVIII mimetic activity

Haemostatic potential of Bi8 in haemophilia A plasma

Viral expression cassette encoding Bi8

AAV-mediated expression of Bi8 in haemophilia A mice

- Dose-dependent expression of Bi8 following AAV-mediated gene transfer
- No evidence of anti-drug antibodies 8-weeks post gene transfer

AAV_Bi8 corrects the bleeding tendency in HA mice

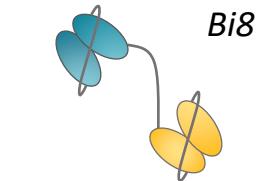

- Expression of single chain Bi8 up to the therapeutic range of the marketed emicizumab antibody
- Significant reduction of blood loss is observed for all tested doses of AAV_Bi8

Overview

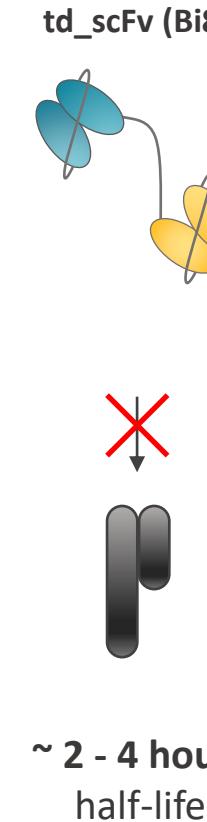

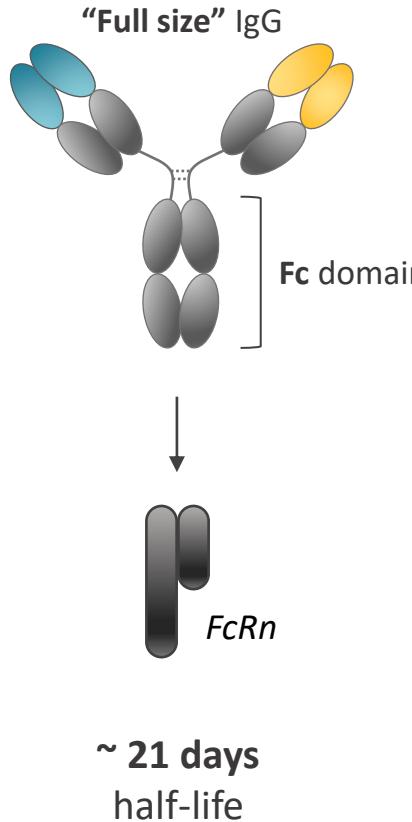

- Bi8 is designed small-sized single chain bispecific antibody with FVIII mimetic activity
- Bi8 enabled the development of a 4.4kb transgenic expression cassette, within the packaging limits of AAV capsids
- Infusion with AAV_Bi8 induces expression of the single chain FVIII mimetic antibody and successfully corrects the bleeding tendency in HA mice
- AAV_Bi8 provides an alternative gene therapy approach for HA which may be applicable to patients with and without FVIII neutralising antibodies

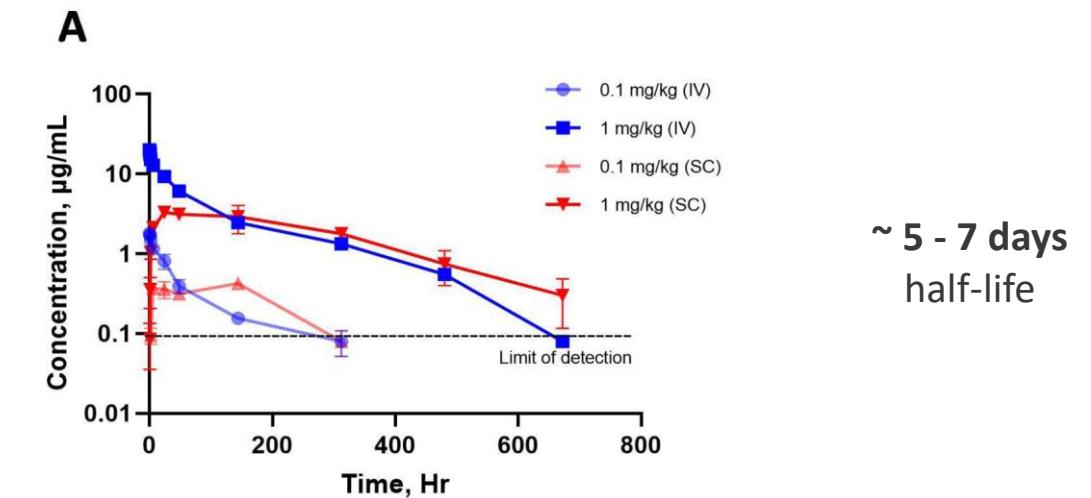

Limitations of gene therapies – the dose of AAV particles

Half-life of a transgene is a limiting factor to maintain high steady-state levels of a protein of interest

- ⇒ The half-life of albumin is also driven by binding to FcRn
- ⇒ **Binding to Albumin can extend the half-life of a protein of interest**
